

Same embedding as a; HH/LL cells are those shown in a (right). Not depth-adjusted.

c HSC-II share along the joint axis

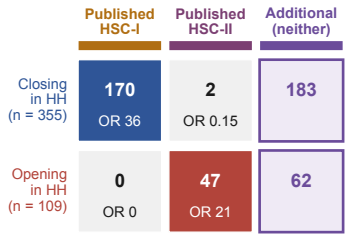

Deciles: all 5,967 scored HSCs. HH and LL (381 each) are selected separately (top or bottom quarter on both contributions, matched on treatment and depth); bars show where they fall.

d Differential accessibility, HH vs LL

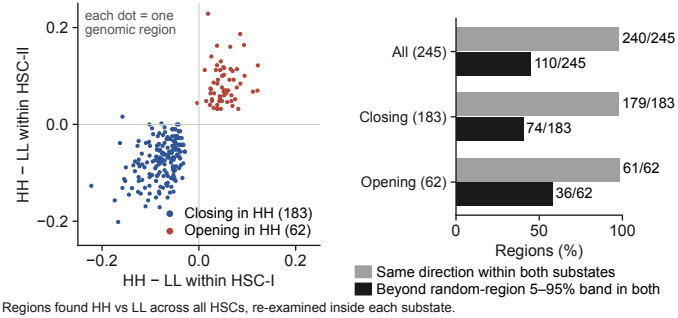

Rows: 464 genomic regions (of 91,517 tested). Columns: fraction of matched cells with the region accessible (white 0, black ≥ 0.4). Same sign in PBS, TNF, LPS: 464/464.

e Overlap with published substate regions

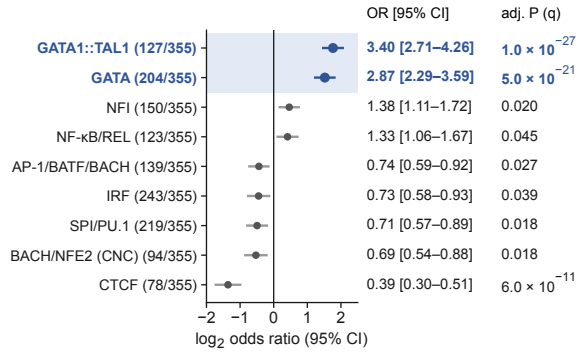

Cells: region counts. Additional regions outside published HSC-I/HSC-II sets: 245 (183 closing, 62 opening).
OR: Fisher odds ratio vs 90,306 tested regions mapped to the published peak set.

f Additional accessibility differences within HSC-I and HSC-II

Regions found HH vs LL across all HSCs, re-examined inside each substate.

g Motif families in the 355 regions closing in HH

Background: tested regions matched on GC, accessibility and width (Mantel–Haenszel). Enrichment is an association; it does not show binding.
